In the last decade there have been numerous advances in the area of rhodium-catalyzed hydroformylation, such as highly selective catalysts of industrial importance, new insights into mechanisms of the reaction, very selective asymmetric catalysts, in situ characterization and application to organic synthesis. The views on hydroformylation which still prevail in the current textbooks have become obsolete in several respects.

Abstract. A rhodium catalyzed one pot hydroformylation of olefins with CO<sub>2</sub>, hydrosilane, and H<sub>2</sub> has been developed that affords the aldehydes in good chemoselectivities at low catalyst loading. Mechanistic studies indicate that the transformation is likely to proceed through a tandem sequence of poly(methylhydrosiloxane) (PMHS) mediated CO<sub>2</sub> reduction to CO and a conventional rhodium catalyzed hydroformylation with CO/H<sub>2</sub>.

Hydroformylation, also known as oxo  
synthesis or oxo process, is an  
industrial process for the production  
of aldehydes from alkenes. This  
chemical reaction entails the net  
addition of a formyl group and a  
hydrogen atom to a carbon-carbon  
double bond. This process has  
undergone continuous growth since  
its invention: Production capacity  
reached  $6.6 \times 10^6$  tons in 1995. It is  
important because aldehydes are

Abstract. A new in situ high-pressure IR (HP-IR) autoclave is presented that is especially suited for mechanistic studies of fast catalytic reactions. This review summarizes several applications of the HP-IR cell in the rhodium catalyzed hydroformylation of alkenes. The most abundant species during the very fast hydroformylation of 1-alkenes using tris (2-tert -butyl-4-methylphenyl) phosphite was identified as the Rh acyl complex  $\text{RhC}(\text{O})\text{R}(\text{CO})_3\text{L}$ .
